For the simple erythema, which may develop after considerable exposure and gives warning to halt before deeper effects are caused, a simple emollient to keep the skin soft and a cessation of X-ray work will usually suffice for treatment. Mr. Kierside, however, finds the following method immediately abortive: At the first sign of erythema, say on the operator's hands, fill two small pails nearly full with water as hot as can be borne. Add a table-spoonful of bicarbonate of soda to each, immerse a hand in each pail, and let them soak in the alkaline solution till the water cools, or about twenty minutes. This has sufficed to at once relieve the effects. For the dry atrophic state into which the fingers and nails of workers sometimes get the negative galvanic current should, on theoretical grounds, do much to restore normal nutrition, but the author has had no case occur in his own practice and hence cannot speak from actual test. The negative galvanic current in a very small amperage is a powerful stimulant of healing processes.

Professor Röntgen, of Würzburg, profiting by Lenard's results, accidentally discovered that the rays coming from a Crookes tube, through the glass itself, could photograph the bones in the living hand, coins inside a purse, and other objects covered up or hid in the dark. Some bodies, such as flesh, paper, wood, ebonite, or vulcanised fibre, thin sheets of metal, and so on, are more or less transparent, and others, such as bones, carbon, quartz, thick plates of metal, are more or less opaque to the rays. The human hand, for example, consisting of flesh and bones, allows the rays to pass easily through the flesh, but not through the bones. Consequently, when it is interposed between the rays and a photographic plate, the skeleton inside is photographed on the plate. A lead pencil photographed in this way shows only the black lead, and a razor with a horn handle only the blade.

Thanks to the courtesy of Mr A. A. Campbell Swinton, of the firm of Swinton & Stanton, the well-known electrical engineers, of Victoria Street, Westminster, a skilful experimentalist, who was the first to turn to the subject in this country, I have witnessed the taking of these "shadow photographs," as they are called, somewhat erroneously, for "radiographs" or "cryptographs" would be a better word, and shall briefly describe his method. Röntgen employs an induction coil insulated in oil to excite the Crookes tube and yield the rays, but Mr Swinton uses a "high frequency current," obtained from apparatus similar

If an acute disease is to be treated, such as streptococcal sepsis, pain, spasms, cramps, etc., apply Oxycodone at once with Vaso-Intensin, two blocks of 5 cc. or in a large syringe of 50 cc. water until the pain is relieved and the disease is checked. Then treat complications by rapidly administering, one to eight hours, or continuous hours, until safe.

violet rays. The irradiated blood is then injected in the patient's venous circulation through closed needles tubing attached to the needle through which the blood was originally withdrawn. The procedure takes about 15 to 20 minutes. In certain cases in the treatment of acute pyogenic infections have been described in detail in original reports by Klotz de Munk, Rabinovitch, Burns, Olsen, and Miley. These favorable clinical results obtained have been shown to be due to a immediate and rapid rise in the patient's own resistance to infection rather than to any direct bactericidal effect, though ultraviolet rays are lethal to all the common causal bacteria. This is not surprising as only 1 per cent of the total blood volume is exposed to ultraviolet light during a blood irradiation. Furthermore, the amount of ultraviolet radiation given is not sufficient to directly kill bacteria in septicemic blood in vitro, although the patient whose septicemic blood was so treated recovered with a rapid disappearance of bacteria from the blood stream, following ultraviolet blood irradiation.		apparently sterilized, as we feel that the results of this therapy must be judged in case differentiation as to the severity and progress of the acute infectious process at the time treatment was initiated.
This rapid rise in resistance to bacterial infection, plus the remarkable safety of the method, naturally suggested the use of blood irradiation in virus and virus-like diseases. The results in these cases prove even here, to date, have been extremely encouraging, in so far as can be judged by careful clinical observation in the cases studied. The difficulties of evaluating the results of any therapy in cases of acute pneumonia and primary septicemia or "virus" pneumonia are fully recognized and appreciated, but facilities do exist in these somewhat artificial climates and we feel that such facilities can be to a great extent prevented by the use of ultraviolet blood irradiation therapy.		The following consecutive cases were studied:

The single case of mumps reported is of interest, because on admission of this individual during a subsequent case, unusually severe symptoms were present, and within twelve hours after the immediate use of ultraviolet blood irradiation therapy, the whole clinical picture had changed completely, with a complete subsidence of toxic symptoms in forty-eight hours. Similar results were complete in four to five days.
